ABSTRACT

Educational institutions generate and store large volumes of student-related data, including academic scores, attendance records, classroom participation, learning activities, and assessment outcomes. Despite the availability of this information, much of the data remains underutilized and is rarely analyzed systematically to improve academic outcomes or guide educational decision-making. Traditional evaluation methods mainly rely on periodic examinations and teacher observations, which often fail to detect early signs of academic decline. As a result, students who struggle academically are frequently identified only after their performance has already deteriorated significantly.

This research explores the application of Educational Data Mining (EDM) techniques to analyze educational datasets and develop predictive models capable of forecasting student academic performance. By leveraging machine learning algorithms, the study aims to identify patterns and relationships within educational data that can be used to predict student outcomes more accurately. Several supervised machine learning models, including Logistic Regression, Decision Tree, Random Forest, and Support Vector Machine (SVM), will be implemented and evaluated to determine their effectiveness in predicting student performance. These models will be trained on educational datasets containing relevant academic and behavioral attributes.

The proposed system focuses specifically on predicting student grades for primary education levels, particularly for students up to Class 6, and categorizing their academic performance into grade levels ranging from A to F. Unlike many existing studies that primarily focus on higher education datasets, this research emphasizes early-stage academic prediction, which is crucial for providing timely educational support during the formative years of learning.

In addition to predicting grades, the study also aims to analyze the underlying factors that may contribute to academic decline. Behavioral and environmental indicators such as excessive mobile phone usage, poor attendance, reduced study engagement, and lack of academic participation will be examined as potential predictors influencing student performance. Identifying these contributing factors can help educators understand not only which students are at risk but also why their performance may be declining.

The predictive models will be evaluated using standard performance metrics including accuracy, precision, recall, and F1-score, ensuring a balanced assessment of model performance across different prediction scenarios. By comparing the performance of multiple algorithms, the study aims to determine the most effective model for educational performance prediction.

The expected outcome of this research is the development of a data-driven predictive framework that can assist educators in early identification of academically at-risk students and support timely academic interventions. Such a system can enhance decision-making in educational institutions, improve teaching strategies, and ultimately contribute to better student learning outcomes.

Keywords: Educational Data Mining, Student Performance Prediction, Machine Learning, Academic Analytics, Early Intervention, Classification Algorithms, Learning Analytics, Educational Data Analysis.

1. INTRODUCTION

The rapid development of digital technologies has significantly transformed modern education systems. Educational institutions increasingly use digital learning platforms, student information systems, and online assessment tools, which generate large volumes of data related to student performance and learning behavior. This data includes academic grades, attendance records, classroom participation, assignment submissions, and other learning activities. While such data holds valuable insights about students' academic progress, it is often stored for administrative purposes and not fully utilized to improve educational outcomes.

Educational Data Mining (EDM) has emerged as an important research field that focuses on applying data mining and machine learning techniques to educational datasets. The primary objective of EDM is to analyze large-scale educational data in order to identify patterns, relationships, and trends that can improve teaching strategies and learning processes. By extracting meaningful knowledge from student data, EDM helps educators better understand student learning behavior and make informed decisions that enhance educational effectiveness.

One of the key applications of Educational Data Mining is student performance prediction. Predicting academic outcomes allows educators to identify students who may be at risk of poor performance at an early stage. Early identification is crucial because it enables teachers and institutions to provide additional support, guidance, and intervention before academic problems become severe. Without such predictive systems, many students are recognized as struggling only after poor examination results or significant academic decline.

Traditional methods for evaluating student performance mainly rely on periodic examinations, assignments, and teacher observations. Although these methods provide basic insights into student progress, they often fail to capture the complex relationships between different factors influencing academic performance. For example, factors such as attendance, study habits, classroom engagement, and behavioral patterns may significantly affect academic success but are difficult to analyze using conventional evaluation approaches.

Machine learning techniques provide powerful tools to address these limitations. Algorithms such as Decision Trees, Random Forest, Support Vector Machines, and Logistic Regression can analyze multiple variables simultaneously and detect patterns within educational data. These models can

predict future academic outcomes based on historical data and identify important factors that influence student performance.

2. MOTIVATION

Education plays a fundamental role in shaping an individual's knowledge, skills, and future opportunities. However, many students experience academic difficulties that are not detected early enough by traditional evaluation systems. In most educational institutions, student performance is primarily assessed through periodic examinations, assignments, and teacher observations. While these methods provide an overview of student progress, they often fail to identify students who may be gradually falling behind in their studies. As a result, students who struggle academically are frequently recognized only after they receive poor grades or fail examinations, leaving limited time for effective academic intervention.

One of the major motivations behind this research is the need for early identification of students at risk of poor academic performance. Early detection allows educators and institutions to take proactive measures such as providing additional academic support, mentoring, or personalized learning strategies. By identifying struggling students at an early stage, educators can help prevent further academic decline and improve overall learning outcomes.

Another motivation is the increasing availability of large educational datasets generated through digital learning environments, school management systems, and online educational platforms. These datasets contain valuable information about student learning behavior, attendance patterns, academic performance, and engagement levels. However, in many cases, this data is not fully utilized for analytical purposes. Applying Educational Data Mining (EDM) techniques can help transform raw educational data into meaningful insights that support data-driven decision-making in educational institutions.

Additionally, most existing research in student performance prediction focuses primarily **on** higher education environments**,** such as universities and online learning systems. There is relatively limited research that focuses on early-stage education, particularly for students in primary school levels. Predicting academic performance at an early stage is important because foundational learning skills are developed during these years. Early prediction can help educators address learning challenges before they significantly affect long-term academic progress.

Another important motivation for this research is the need to understand the factors contributing to declining academic performance**.** Academic outcomes are influenced by multiple variables, including study habits, attendance, classroom engagement, and behavioral factors such as excessive mobile phone usage. Identifying these factors can help educators understand why certain students struggle academically and develop targeted strategies to support them.

Therefore, this research is motivated by the goal of developing a data-driven predictive system that can analyze educational data, predict student performance accurately, and provide insights into the underlying factors affecting academic success. Such a system can assist educators in making informed decisions, improving teaching strategies, and ultimately enhancing student learning outcomes.

3. LITERATURE REVIEW

Educational Data Mining (EDM) has become an important research area that focuses on analyzing educational datasets using data mining and machine learning techniques. With the growing use of digital learning platforms, learning management systems, and student information systems, educational institutions now collect large volumes of data related to student activities, academic performance, attendance, and learning behavior. Researchers have explored various approaches to utilize this data in order to understand student learning patterns and improve academic outcomes.

Several studies have investigated the application of machine learning techniques to predict student academic performance. Commonly used algorithms include Logistic Regression, Decision Trees, Random Forest, Support Vector Machines, and Neural Networks. These models analyze multiple variables such as attendance records, assignment scores, study time, and demographic information to predict academic outcomes. Many studies have reported that ensemble learning methods, particularly Random Forest, perform well in educational datasets because they can handle complex relationships among variables and reduce the risk of overfitting.

Systematic reviews of educational data mining research show that EDM techniques are widely applied in tasks such as student performance prediction, student modeling, behavior analysis, and personalized learning systems. In addition to classification techniques, clustering algorithms have also been used to group students based on their learning behavior or academic performance. This grouping helps educators identify patterns among students and provide targeted academic support. However, most existing studies focus primarily on improving prediction accuracy rather than explaining the factors influencing student performance.

Recent research also highlights the importance of model interpretability in educational analytics. Explainable artificial intelligence techniques are increasingly used to identify the most important variables influencing machine learning predictions. Methods such as feature importance analysis, SHAP values, and LIME help researchers understand how different variables contribute to the predicted outcomes. This improves the transparency of machine learning models and allows educators to better interpret the results.

Some recent studies have also explored the integration of emerging technologies with educational data mining. For example, immersive learning environments such as virtual and augmented reality systems allow researchers to collect detailed data about student engagement and learning behavior. The analysis of such data can provide deeper insights into student learning processes and academic

development.

Despite these advancements, a significant portion of existing research focuses on higher education datasets and limited academic indicators. There is relatively less research that focuses on predicting performance at early stages of education or analyzing behavioral factors that influence academic outcomes. This creates an opportunity for further research in early academic performance prediction and identification of factors contributing to declining student performance.

Table: Sample of Literature Review Table

Author	Sample/Data	Title	Source	Findings
Romero & Ventura (2013)	Multiple educational datasets from previous EDM studies	Educational Data Mining: A Review of the State of the Art	IEEE Transactions on Systems, Man, and Cybernetics	Educational Data Mining techniques help analyze student behavior and predict academic performance using machine learning models.
Dutt, Ismail & Herawan (2017)	Literature from 1983–2016 on clustering in education	A Systematic Review on Educational Data Mining	IEEE Access	Clustering is widely used as a preprocessing technique in EDM to identify student learning patterns and group similar learners.
Papamitsiou & Economides (2014)	Learning analytics and educational datasets	Learning Analytics and Educational Data Mining in Practice	Educational Technology & Society	Machine learning and analytics techniques help improve learning outcomes through data-driven educational decisions.

4. Gap Analysis

Although significant research has been conducted in the field of Educational Data Mining, several limitations and research gaps still exist. Many existing studies focus mainly on analyzing educational datasets from higher education institutions such as universities and online learning platforms. These studies often examine student performance at the college or university level, while relatively fewer studies focus on early-stage education such as primary school students. Early academic stages are critical because foundational learning skills and study habits are developed during this period. Predicting academic performance at this stage can help educators identify potential learning difficulties much earlier.

Another limitation observed in existing research is that many studies focus primarily on improving prediction accuracy using machine learning models. While achieving high accuracy is important, less attention is often given to understanding the underlying factors that influence student performance. As a result, many predictive models function as black-box systems that generate predictions without providing clear explanations about why certain students perform better or worse academically.

In addition, most research studies rely mainly on traditional academic variables such as exam scores, assignment marks, or attendance records. Although these factors are important, academic performance is also influenced by behavioral and environmental factors such as study habits, classroom engagement, learning motivation, and technology usage patterns. These aspects are often not sufficiently explored in many existing studies, creating a gap in understanding the broader causes of academic performance variations.

Another gap relates to the practical application of predictive systems in real educational environments. Many studies focus on algorithm development and experimental evaluation but do not clearly demonstrate how the prediction results can support real-time academic intervention by educators. For predictive systems to be useful in educational settings, they must provide actionable insights that help teachers identify struggling students and implement timely support strategies.

Furthermore, most existing research focuses only on predicting whether a student will pass or fail, rather than predicting detailed performance categories. Predicting performance in structured grade categories can provide more meaningful insights for educators and help monitor academic progress more effectively.

This research aims to address these gaps by focusing on early-stage education, predicting student grades within a structured range from A to F, and identifying potential behavioral factors that may

contribute to declining academic performance.

4. Problem Statement

Educational institutions generate large volumes of student-related data such as academic scores, attendance records, classroom activities, and assessment results. Despite the availability of this data, many institutions do not effectively utilize it to gain insights into student learning patterns or academic performance. Traditional evaluation methods mainly rely on periodic examinations and manual observation by teachers, which often provide limited understanding of the factors affecting student performance. As a result, students who may be at risk of poor academic outcomes are often identified only after their grades decline significantly.

One of the major challenges faced by educators is the difficulty in detecting academic issues at an early stage. Without early identification, students may continue to struggle academically, leading to poor learning outcomes and reduced confidence in their academic abilities. Therefore, there is a growing need for intelligent systems that can analyze educational data and provide early predictions about student performance.

Educational Data Mining offers powerful techniques that can analyze large educational datasets and identify hidden patterns within them. Machine learning algorithms can process multiple variables simultaneously and detect relationships between factors such as attendance, study habits, learning engagement, and academic results. By using these techniques, it becomes possible to predict student performance and identify students who may require additional academic support.

However, many existing studies focus primarily on predicting performance in higher education or simply classifying students as pass or fail. Such approaches may not provide sufficient detail about a student's academic progress. Predicting performance using detailed grade categories can provide a clearer understanding of academic levels and allow educators to monitor improvement or decline more effectively.

In addition, academic performance can be influenced by several behavioral factors such as excessive mobile phone usage, poor study habits, and low classroom engagement. Identifying these factors is important for understanding the reasons behind declining academic performance and enabling educators to implement targeted interventions.

Therefore, the main problem addressed in this research is the development of a predictive system that uses educational data mining techniques to analyze student data, predict academic performance in grade categories ranging from A to F for students up to Class 6, and identify factors that may contribute

to declining academic performance. Such a system can help educators detect at-risk students earlier and support timely academic intervention.

6. Objectives

The main objective of this research is to apply Educational Data Mining techniques to analyze student data and develop a predictive model capable of forecasting academic performance. By analyzing educational datasets and identifying meaningful patterns, the study aims to assist educators in understanding the factors that influence student performance and enable early identification of students who may be at risk of academic decline.

The specific objectives of this research are as follows:

1. To analyze educational datasets containing information such as student grades, attendance records, and learning activities in order to understand patterns related to student performance. Data preprocessing techniques will be applied to clean the dataset, handle missing values, and prepare the data for machine learning analysis.
2. To develop predictive models using multiple machine learning algorithms such as Logistic Regression, Decision Tree, Random Forest, and Support Vector Machine. These models will be trained on historical student data to predict academic performance and evaluate how effectively each algorithm can classify student outcomes.
3. To compare the performance of different machine learning models using evaluation metrics such as accuracy, precision, recall, and F1-score. This comparison will help determine the most suitable model for predicting student grades and ensure the reliability of the prediction system.
4. To classify student performance into structured grade categories ranging from A to F for students up to Class 6. This approach provides a more detailed representation of academic performance compared to simple pass or fail classifications and allows educators to better monitor student progress.
5. To identify key factors influencing student performance, including academic indicators and behavioral aspects such as attendance, engagement, and possible external influences like excessive mobile phone usage. Understanding these factors can help educators recognize the reasons behind declining academic performance.

By achieving these objectives, the research aims to develop a predictive framework that supports data-driven decision-making in education.

7. Tools / Platform Used

The successful implementation of the proposed student performance prediction system requires the use of several software tools, programming environments, and machine learning libraries. These tools help in data preprocessing, model development, visualization, and evaluation of results. The project primarily relies on widely used open-source technologies that support efficient data analysis and machine learning implementation.

The primary programming language used in this research is Python, which is widely recognized for its simplicity, flexibility, and strong support for data science and machine learning applications. Python provides a rich ecosystem of libraries that enable efficient data manipulation, statistical analysis, and model development. Its extensive community support and availability of machine learning frameworks make it an ideal choice for implementing Educational Data Mining techniques.

For data manipulation and preprocessing, libraries such as Pandas and NumPy are used. Pandas provides powerful data structures that allow efficient handling of structured datasets, including tasks such as data cleaning, filtering, and transformation. NumPy supports numerical computations and enables efficient handling of arrays and mathematical operations that are commonly required during machine learning model training.

The machine learning models used in this research are implemented using the Scikit-learn library. Scikit-learn provides a comprehensive set of algorithms for classification, regression, clustering, and model evaluation. Algorithms such as Logistic Regression, Decision Tree, Random Forest, and Support Vector Machine can be easily implemented and compared using this framework. In addition, Scikit-learn includes built-in tools for model evaluation using metrics such as accuracy, precision, recall, and F1-score.

For data visualization and graphical representation of results, libraries such as Matplotlib and Seaborn are used. These libraries help generate charts, graphs, and visualizations that make it easier to interpret patterns in the data and present findings clearly.

The development and experimentation process is carried out using Jupyter Notebook, which provides an interactive environment for writing code, executing analysis, and documenting results. Jupyter Notebook allows researchers to combine code, visualizations, and explanations in a single document, making it convenient for experimentation and presentation of results.

Together, these tools provide a comprehensive platform for implementing the proposed Educational Data Mining framework and developing an effective student performance prediction system.

8. Methodology

The methodology of this research focuses on applying Educational Data Mining techniques and machine learning algorithms to analyze educational datasets and predict student academic performance. The process is structured into multiple stages to ensure systematic analysis, accurate model development, and reliable prediction results.

1. Data Collection

The first stage involves collecting a suitable educational dataset that contains relevant student information. The dataset includes variables such as academic scores, attendance records, learning activities, and other behavioral attributes related to student performance. The dataset is structured so that the final output variable represents student grades categorized from A to F for students up to 6.

2. Data Preprocessing

Raw educational data often contains missing values, inconsistent records, and categorical attributes that cannot be directly used by machine learning models. Therefore, data preprocessing is performed to prepare the dataset for analysis. This step includes handling missing values, removing duplicate or irrelevant data, encoding categorical variables, and normalizing numerical attributes when required. Proper preprocessing improves the quality of the dataset and helps in building more reliable predictive models.

3. Data Splitting

After preprocessing, the dataset is divided into two parts: a training dataset and a testing dataset. The training dataset is used to train machine learning models, while the testing dataset is used to evaluate how well the trained models perform on unseen data. This step helps measure the generalization capability of the models.

4. Model Development

Several supervised machine learning algorithms are applied to predict student performance. The models used in this research include Logistic Regression, Decision Tree, Random Forest, and Support Vector Machine. Each algorithm analyzes the relationship between input variables and the target variable to predict student grades.

5. Model Evaluation

The performance of the models is evaluated using standard evaluation metrics such as accuracy, precision, recall, and F1-score. These metrics help determine how effectively each algorithm predicts student grades. A comparison of the models is conducted to identify the most accurate and reliable predictive model.

6. Interpretation of Results

The final stage involves analyzing the results produced by the best-performing model. The system identifies key factors influencing student performance and highlights possible reasons for declining grades, such as low attendance, poor study engagement, or excessive mobile phone usage. These insights can assist educators in identifying at-risk students and implementing timely academic interventions.

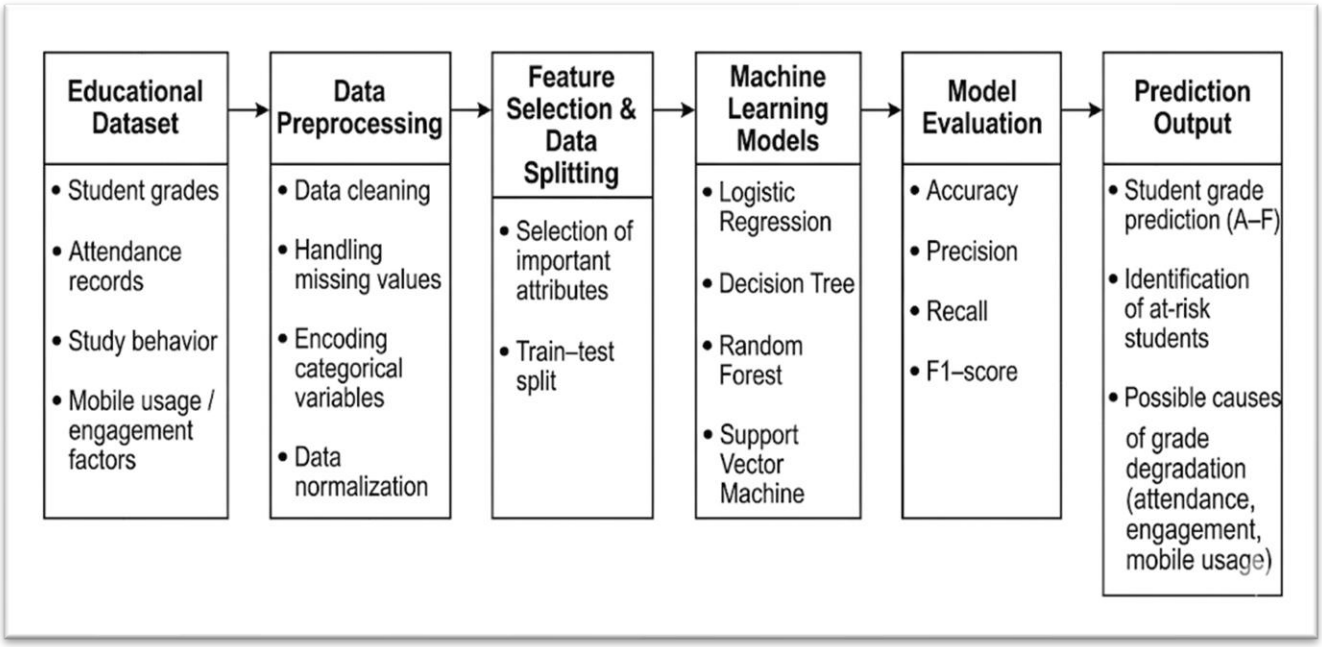

Figure 1: Architectural Diagram

This diagram illustrates the architecture of the proposed student performance prediction system using Educational Data Mining. The process begins with collecting educational data, followed by preprocessing and feature selection to prepare the dataset for analysis. Machine learning models are then applied and evaluated to predict student grades (A–F) and identify at-risk students along with possible factors affecting their academic performance.
